

Using GIS Tools to Target Health Disparities Interventions

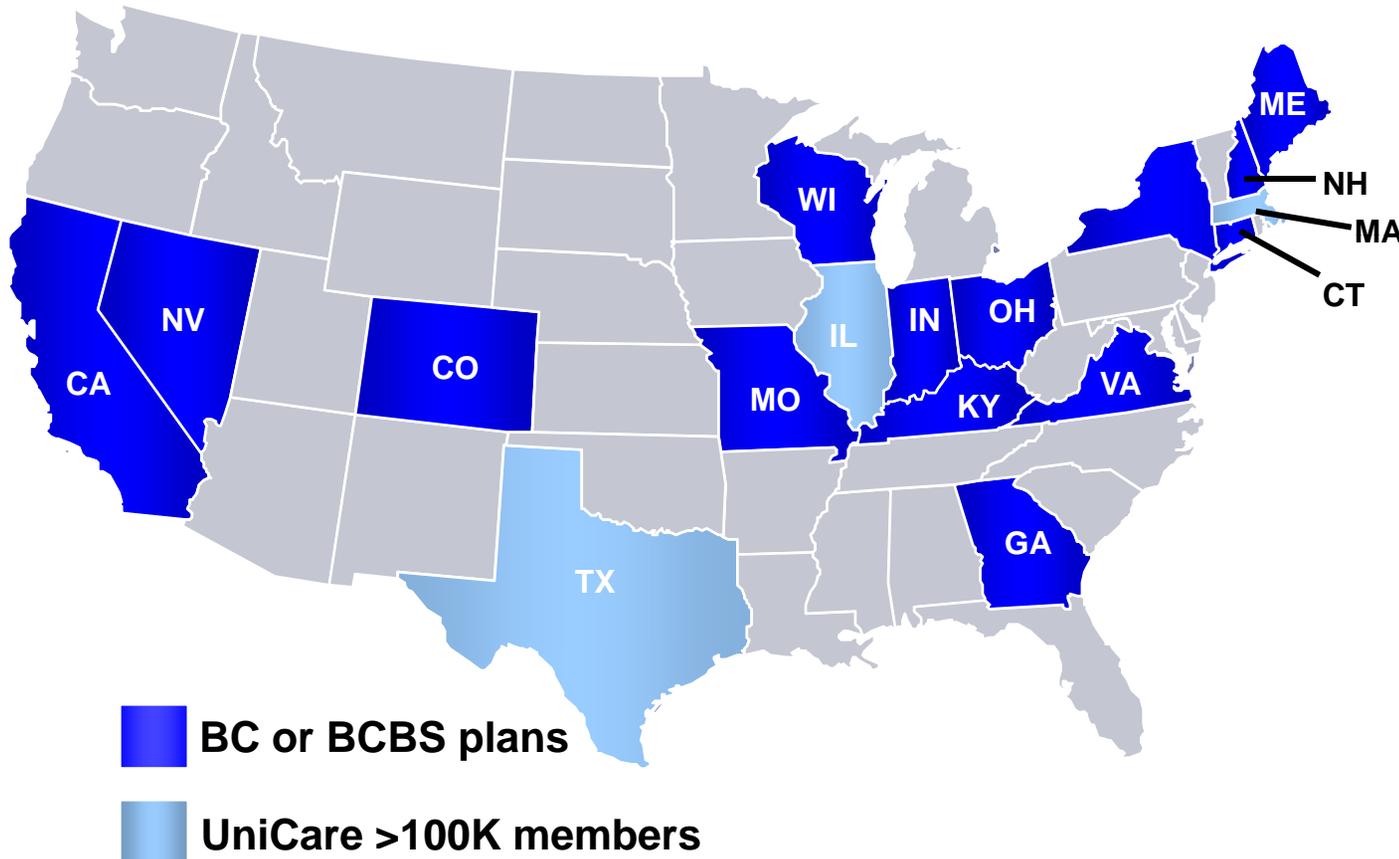

Zachary Vernon

**Sr. Health Information Consultant
Programs in Clinical Excellence**

**2008 ESRI Health GIS Conference
September 29, 2008**

WellPoint, Inc.

35 Million Members Across the Country

Health Disparities – A Few Statistics

- African Americans have the highest rate of high blood pressure of all racial/ethnic groups and tend to develop it younger than others
- Compared to Whites, African Americans and Hispanic are more than twice as likely to have diabetes
- In 2002 in the United States more than 2 1/2 times as many African American newborn babies died (14.1 per 1,000 live deaths) as white newborns
- Among African American Mothers with college educations, infant mortality rates are almost 3 times higher than the rates for White mothers with the same level of education

Projected Life Expectancy from Birth - 1999

	White	Asian	Hispanic	African American
Male	74.7	80.8	77.1	68.3
Female	80.1	86.5	83.7	75.1

* Based on Data from U.S. Census

The Problem We Face

- The collection of data on race, ethnicity, and primary language of enrollees are key steps in the implementation of targeted interventions for improving overall quality and reducing racial and ethnic disparities in health and health care
- Fundamental barriers to the collection of such data exist
 - Commercial plans, which cover the majority of insured in the United States, still have limited race/ethnicity data on their enrolled members
 - Enhancements and upgrades of the technological infrastructure and databases needed to house the data are expensive investments
 - Redesign of work flows and data processes to collect the data systematically also require significant investment in human resources and training costs
 - The actual process can take years to complete, or reach a saturation point where a portion of the insured will always decline to provide such data

Addressing the Problem

WellPoint, Inc. (WellPoint) historically did not collect data in regard to the race/ethnicity of its members.

- Established the Health Disparities Analytic Unit
- Consulted with the RAND Corporation to learn more about indirect models and GIS Tools
- Developed a proxy methodology to derive indirect race and ethnicity information for members
- Used GIS Tools along with traditional analysis techniques to plan quality interventions

What is Proxy Methodology

- At Wellpoint, we developed a statistical methodology that allows the prediction of race/ethnicity
- The methodology utilizes
 - Enrollee first and last names
 - Enrollee residential address
- First names are matched to an internally developed list of African American first names
- Surnames are matched to a series of surname list from the U.S. Census
- Through geocoding, addresses are linked to Census data based upon an enrollees neighborhood
- These factors are linked together using logistic regressions to determine the probability that a person is Asian, African American, Hispanic, or White/other

Components of Indirect Methodology

Surname Lists

- In 2007 the U.S. Census published a list of all names appearing more than 100 times in the 2000 Census
- Demographic data was also included for these names

Name	Rank	White (%)	African American (%)	Asian Pacific Islander (%)	Native American (%)	2 or More Races (%)	Hispanic (%)
SMITH	1	73.35	22.22	0.40	0.85	1.63	1.56
RODRIGUEZ	9	5.52	0.54	0.58	0.24	0.41	92.70
WILLIAMS	3	48.52	46.72	0.37	0.78	2.01	1.60
RODRIGUEZ	9	5.52	0.54	0.58	0.24	0.41	92.70
LEE	22	40.09	17.41	37.83	1.03	2.30	1.34
KIM	109	2.60	0.36	94.52	0.03	1.99	0.50

* Data from US Census Bureau - <http://www.census.gov/genealogy/www/freqnames2k.html>

Components of Indirect Methodology

First Name Lists

- Surnames are not as helpful in identifying African American enrollees
- Developed first name list to help
- First name lists could be developed to identify other ethnicities

Name	Rank	African American (%)
MICHAEL	1	12.80
LATOYA	27	89.69
EBONY	29	77.75

* Data developed internally by Anthem Blue Cross

Components of Indirect Methodology

Geocoding

- Determines the physical location of an address (latitude, longitude)
- Currently use a vendor for data scrubbing and geocoding
- Allows linking to Census Data for a specific census tract or block
- Other Census data such as wages, education, language, etc. can also be added

Los Angeles County, CA – Census Tract 1041.07 – Block Group 1					
Total Population	White / Other (%)	African American (%)	Asian (%)	Hispanic (%)	Median Household Income
552	68.5	8.7	2.4	20.4	\$46,042

* Data from 2000 Census

Components of Indirect Methodology

Logistic Regression

- Combines name and location data
- Calculates probability that enrollee is White/Other, African American, Asian, and Hispanic

Member	White / Other (%)	African American (%)	Asian (%)	Hispanic (%)
A	72.5	7.4	7.7	12.4
B	3.6	0.5	2.0	93.8
C	42.4	54.7	0.9	2.0

Is Indirect Methodology Really Reliable?

Accuracy Rate – Population Aggregate

Aggregate Data

- Indirect methods have high degree of accuracy when comparing population groups

Aggregate Demographics – Predicted vs. Reported

Approach N = 192,096	Hispanic (%)	Asian (%)	Black (%)	White / Other (%)
Surname Only	46.1	6.6	7.1	40.2
Geocoding Only	41.3	7.9	11.9	39.0
WellPoint Model	52.1	7.9	14.7	25.3
Member Self – Reported Data	52.0	8.0	14.8	25.2

Is Indirect Methodology Really Reliable?

Accuracy Rate – Individual Member Level

Individual analysis

- Indirect methods show strong potential in identifying the R/E of individual members (86.2% of the validation set identified correctly)

Individual R/E Correctly Predicted

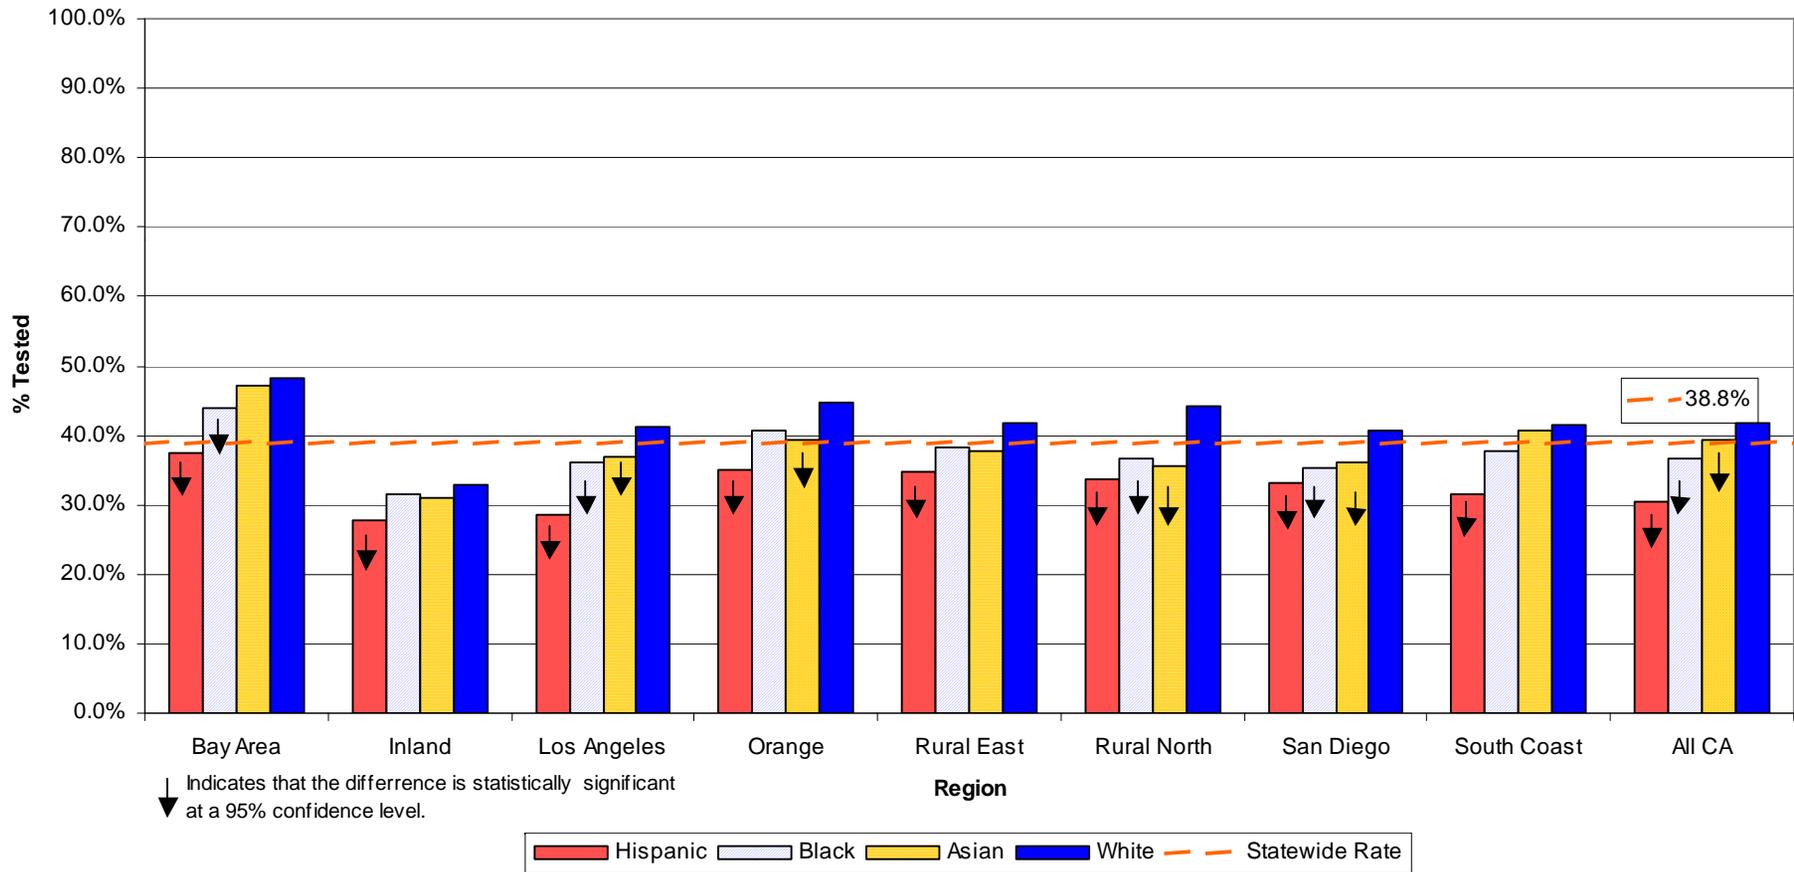

Approach N = 192,096	All Members Accuracy Rate	Over 80% Accuracy Rate	Over 80% Member Count
Surname	74.5%	90.8%	130,150
Geocoding	62.9%	84.4%	54,092
Logistic Model	86.2%	93.8%	145,009

Combining Indirect Methodology & HEDIS

- HEDIS data is a good starting point for investigating health disparities
 - Data already exists
 - Focused on key health elements
- By Applying Proxy Methodology HEDIS rates can be estimated by Race/Ethnicity
- Traditional Analysis and GIS Tools allow visualization and investigation on many levels
 - Region
 - County
 - Zip code
 - Provider

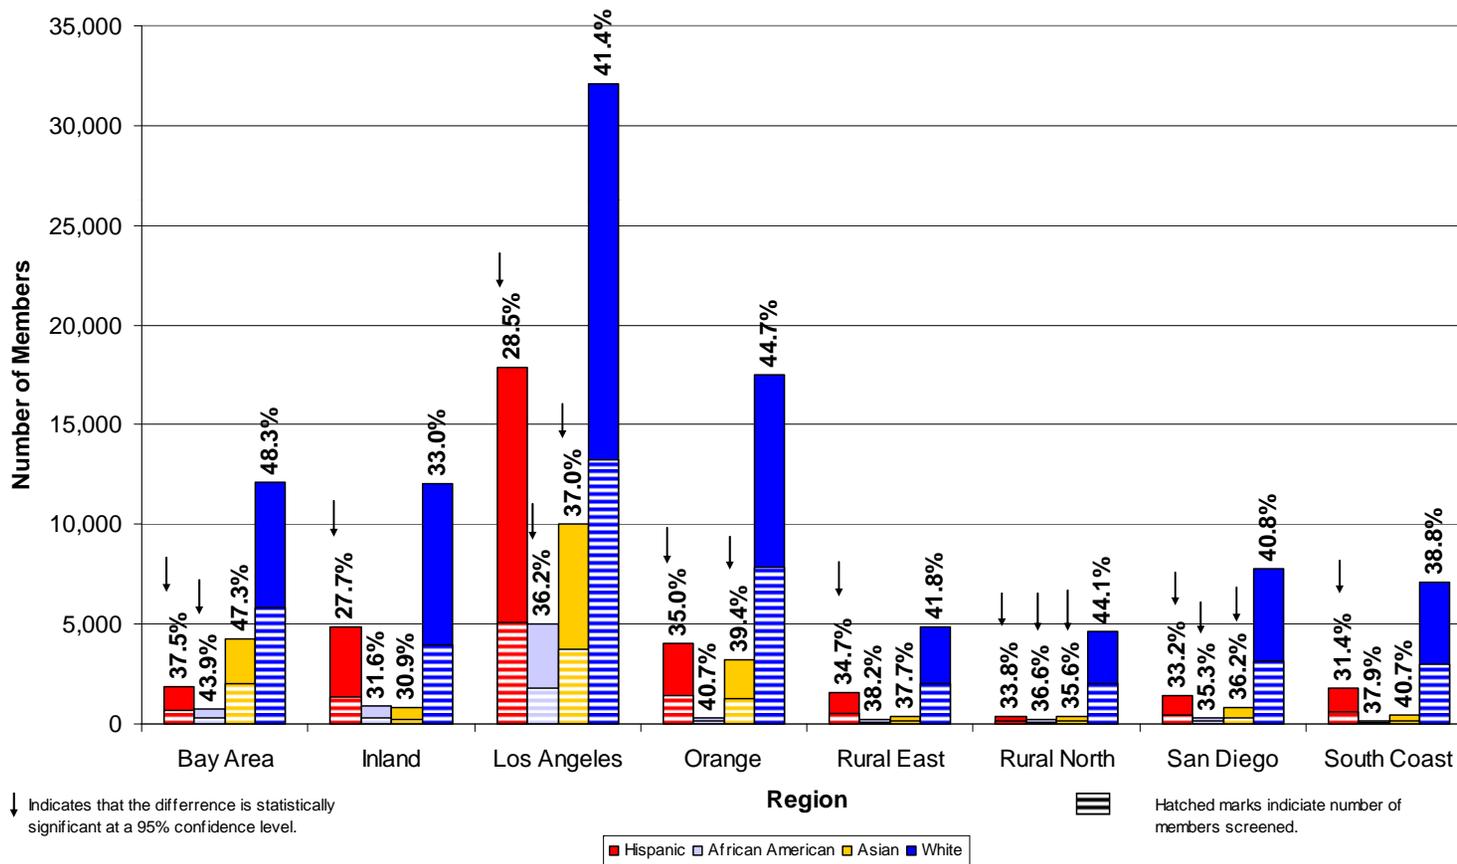

Traditional Rate Analysis

Colorectal Cancer Screening by CA Region

Analysis of Volume

Colorectal Cancer Screening Populations and Screening Rates by CA Region

Intervention and Implementation

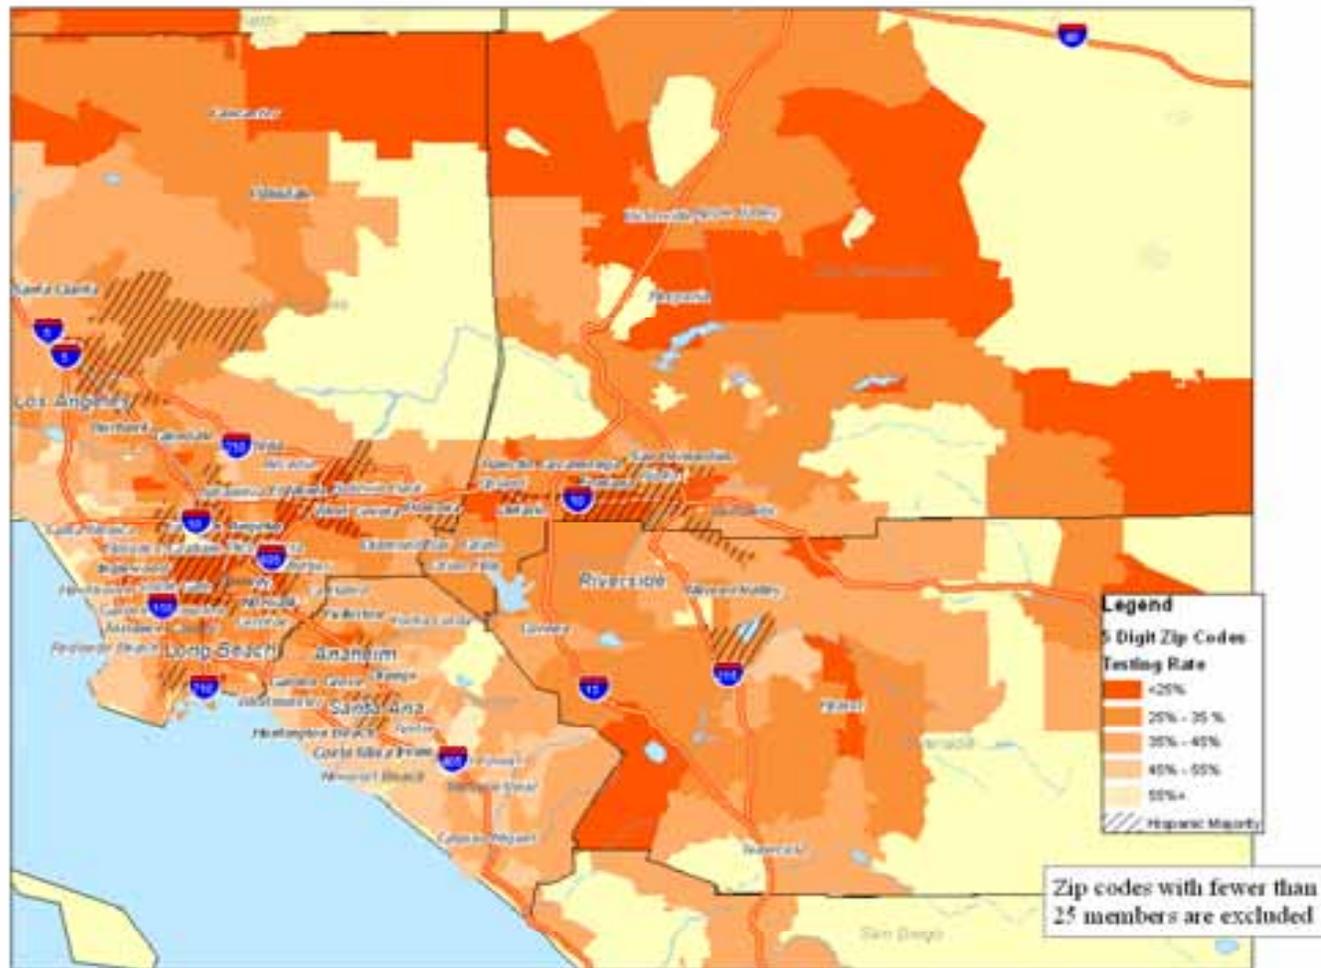

Applications of GIS Mapping Tools

- Geocoding has the added benefit of allowing members to be tied to Census and geographic data
- Additional, Census data can include education levels, language proficiency, income, etc.
- GIS applications facilitate visual drill down to community and individual hotspots

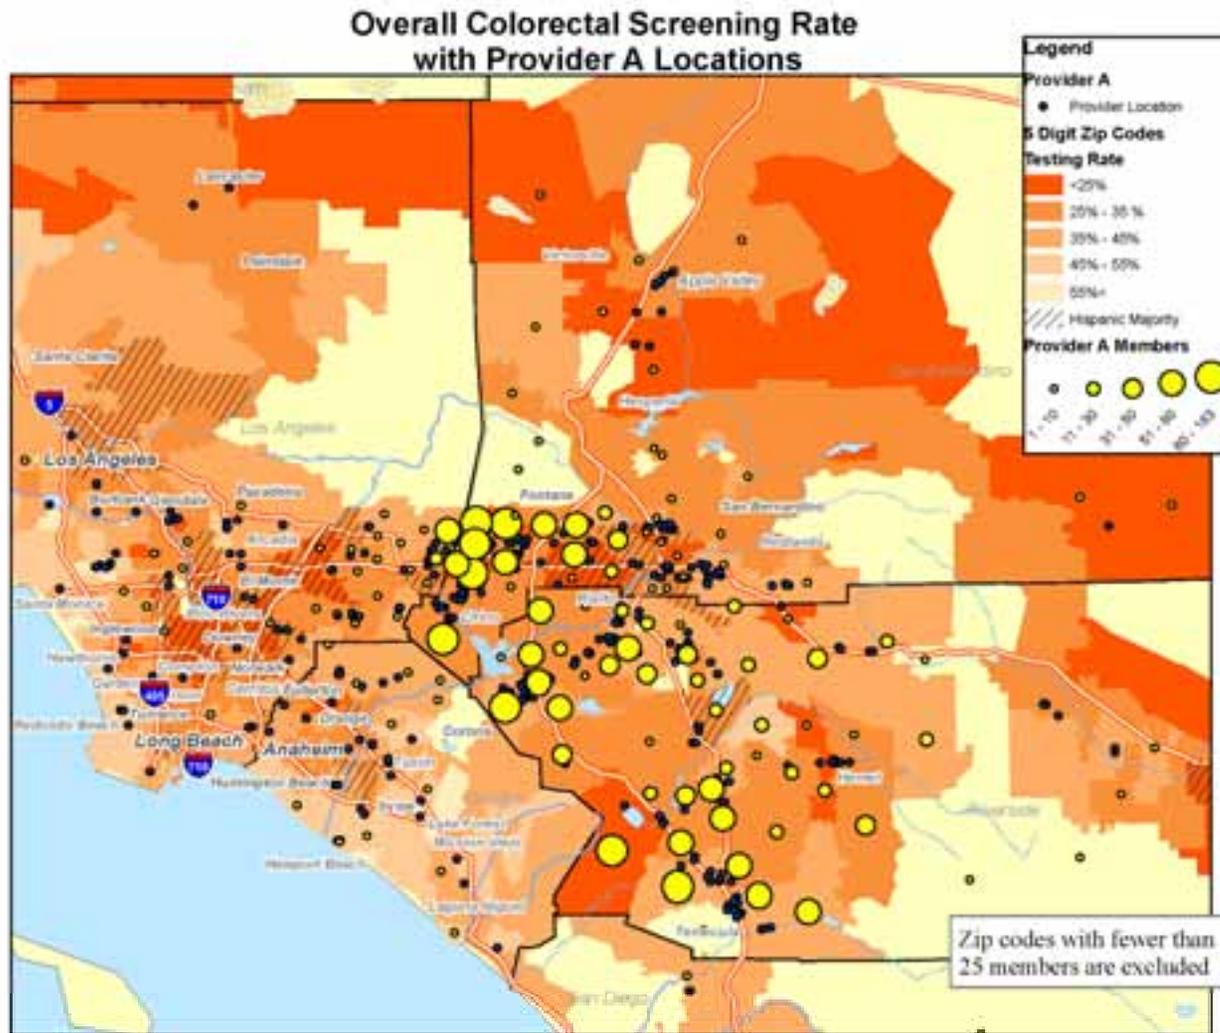

Drilldown to Region

Overall Colorectal Screening Rate

Provider Locations

Provider Dashboard

Provider Dashboard Colorectal Screening

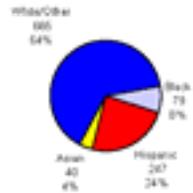

Provider & Region
Provider A (Inland)

Overall	Disparity
Above Average	Yes

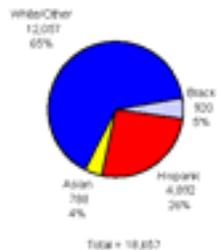

Provider R / E Mix (Number of Patients)

Race	Hispanic	Asian	White/Other	Total
79	247	40	665	1,031

Estimated Racial / Ethnic Demographics Colorectal Screenings Provider A (Inland)

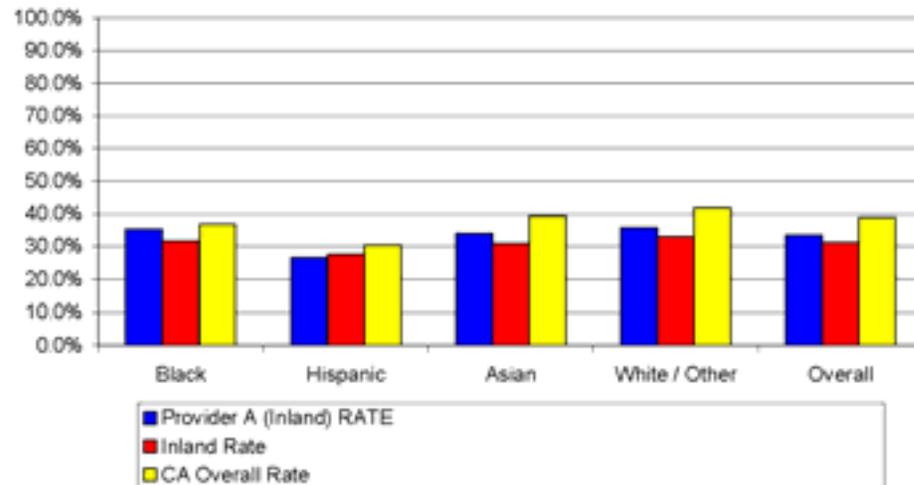

Estimated Racial / Ethnic Demographics Colorectal Screenings Inland

Overall Performance	
CA Overall Rate	35.0%
Inland Rate	31.1%
Provider A (Inland) RATE	33.4%
2.3% Above Average Inland Rate	

Performance By R / E	Black	Hispanic	Asian	White / Other	Overall
CA Overall Rate	35.0%	35.2%	32.2%	41.2%	35.0%
Inland Rate	31.6%	27.3%	30.9%	33.0%	31.1%
Provider A (Inland) RATE		35.2%	26.6%	34.0%	35.1%
Difference vs Inland Rate	3.5%	-1.1%	-3.5%	2.3%	2.3%
Difference vs White / Other Treated by Provider	-0.6%	-0.1%	-1.1%		
Disparity vs White / Other Treated by Provider (95% Confidence)	No	Yes	No		

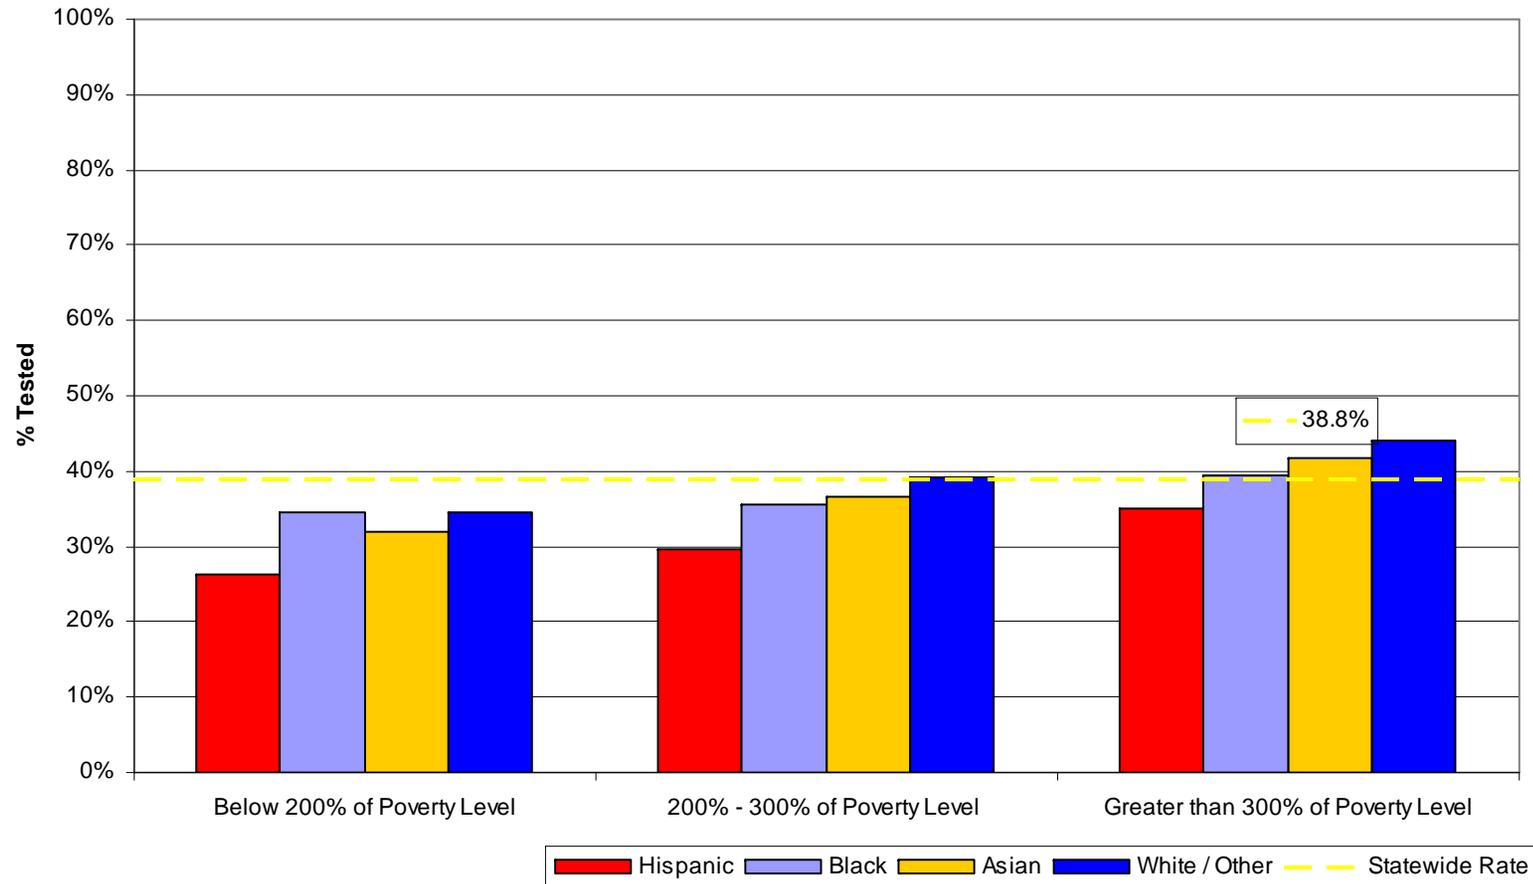

Performance by Race / Ethnicity

Geocoding – Provides a Link to Data

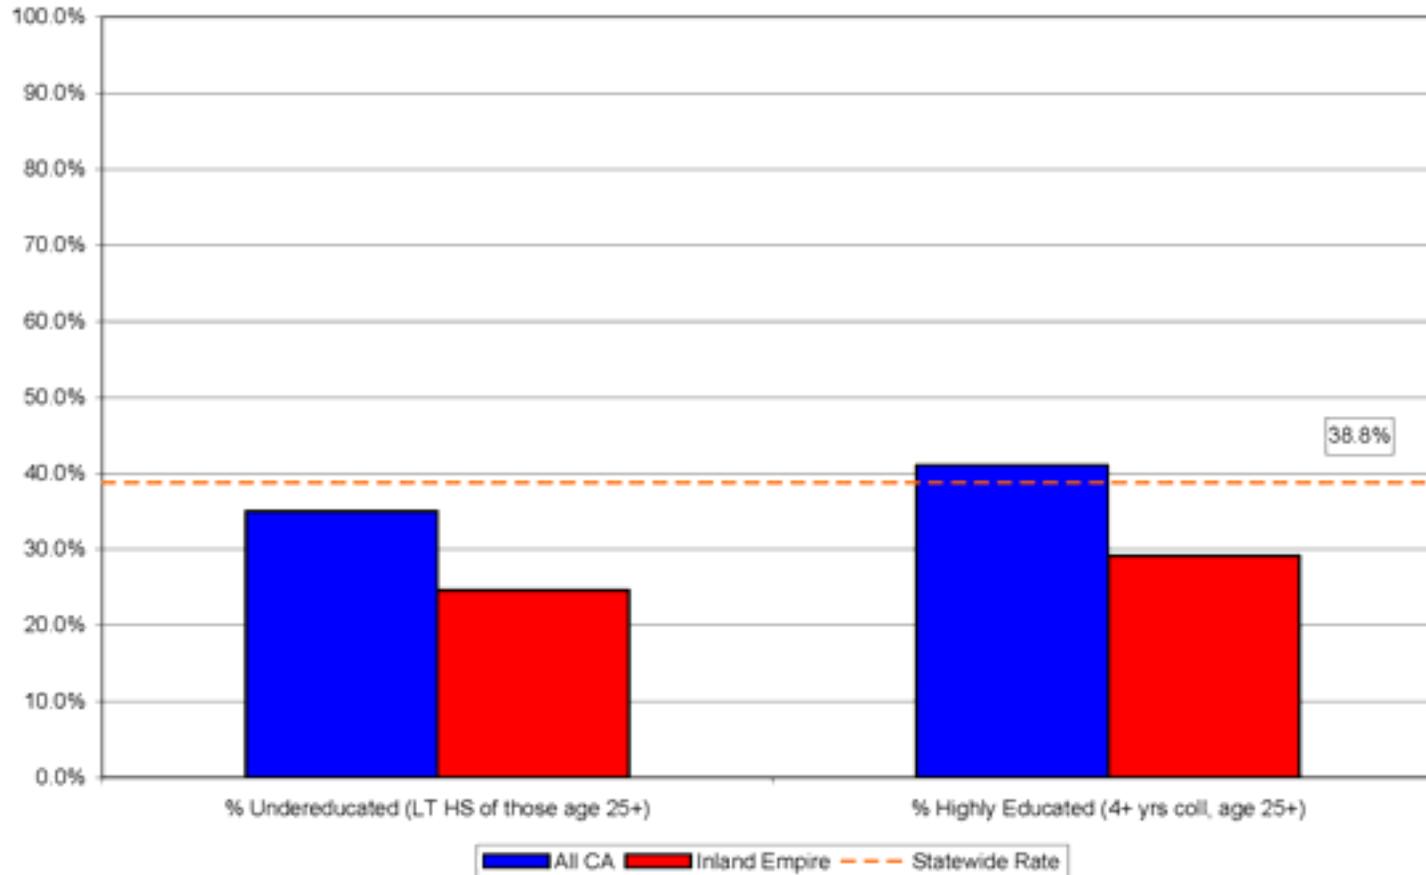

Colorectal Screening Rates by Poverty Level and Race

Poverty Level is \$17,603 for a 4 person household - 2000 Census

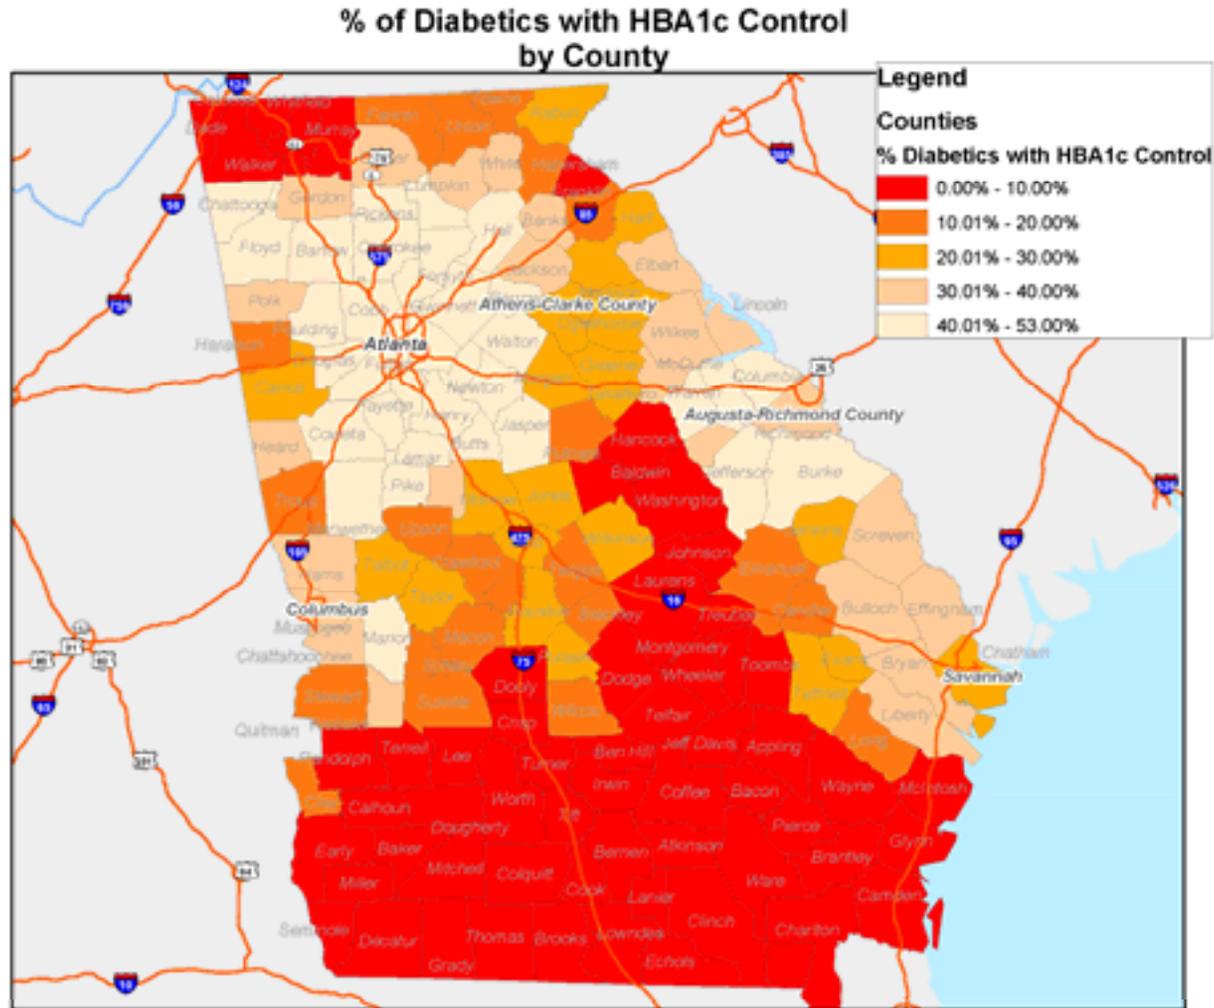

Census Data Provides Insight

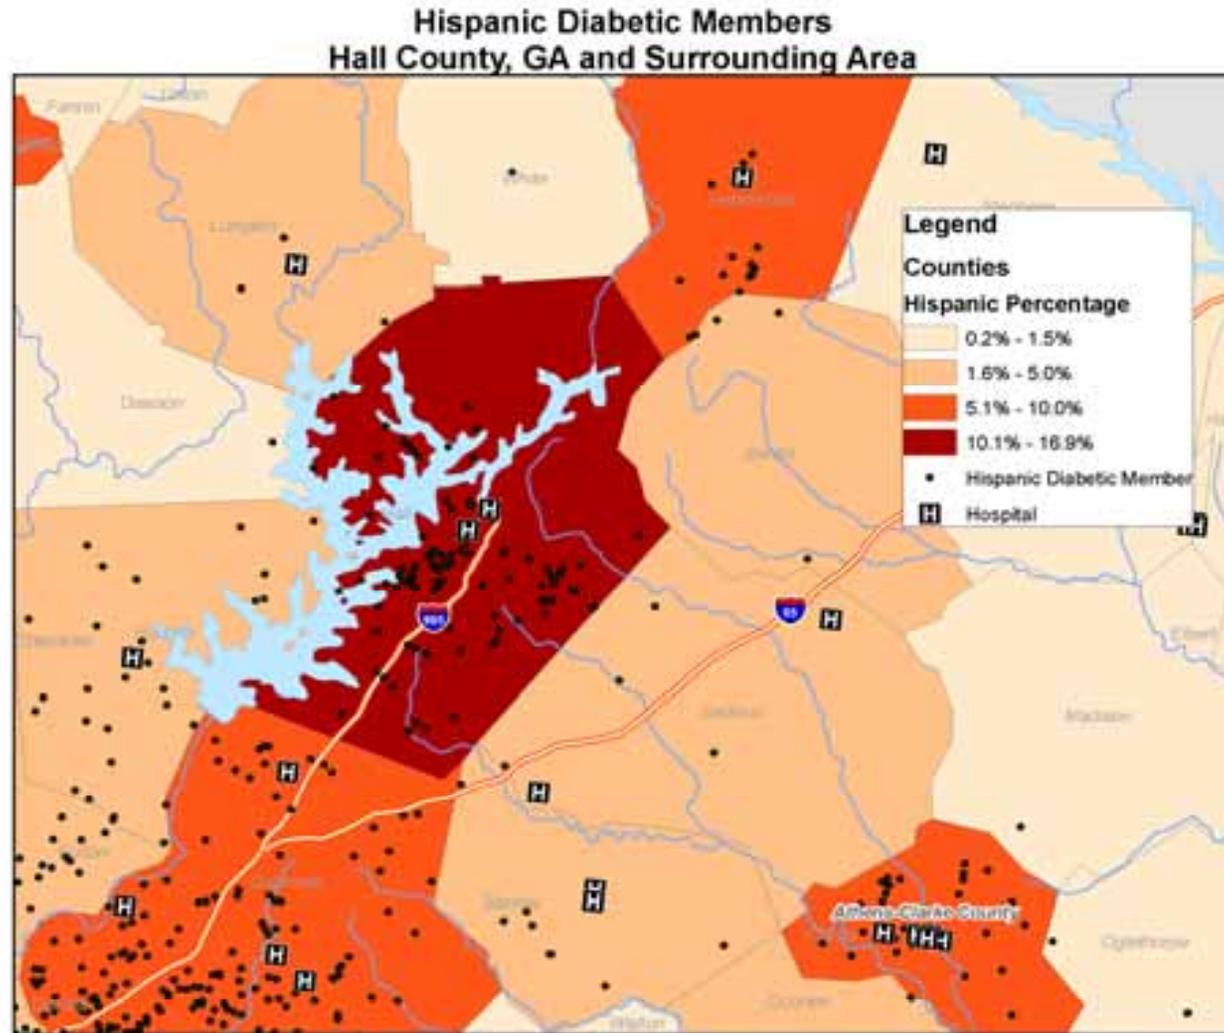

Comparison of Testing Rate by Education Level

Determining Best Locations for Telemedicine

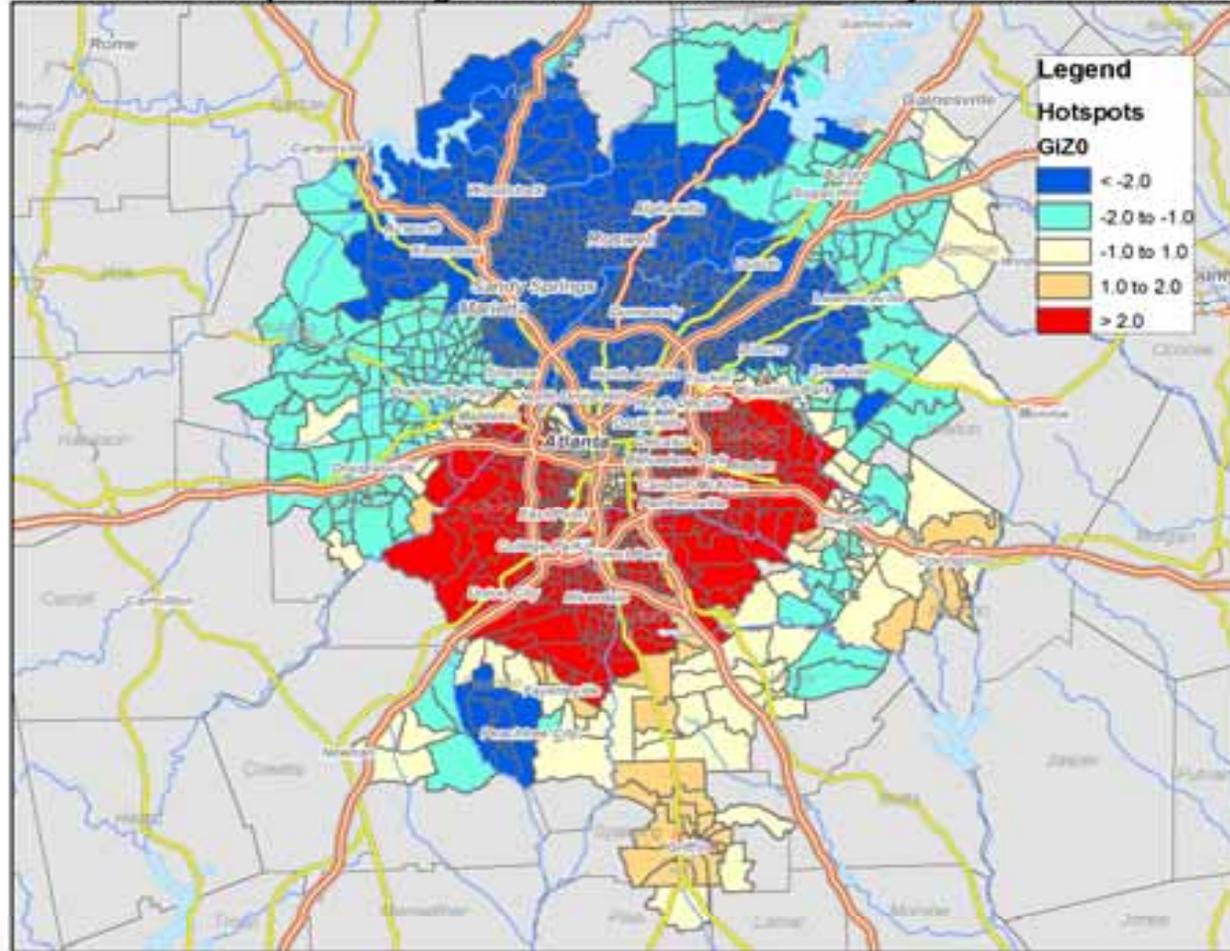

Hall County Georgia – Hispanic Diabetics

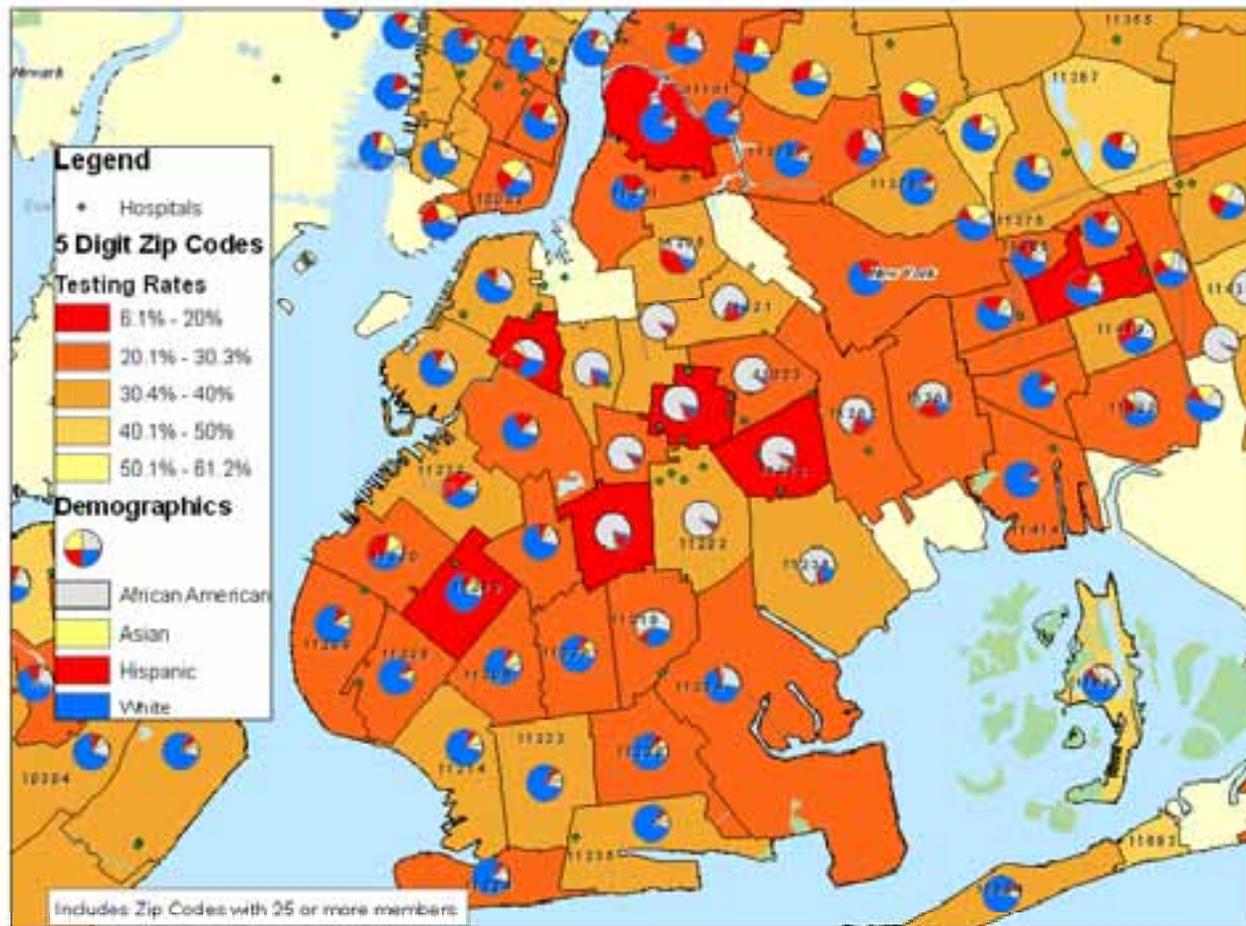

Atlanta – Locating Unscreened Hot Spots

**Atlanta Mammography Screening Rates
Unscreened Hotspots Among African American Members by Census Block Group**

Brooklyn - Combining Demographics and Rates

Brooklyn - Rates by Zip Code
Mammography Testing Rates

How is the Analysis Used

- The logistic model of indirect race/ethnicity data methodology has proven itself to be flexible and applicable to address a wide range of project and business support needs
 - Used to identify hotspots of unscreened members
 - Study provider access for minority members
 - Identify minority members for culturally/linguistically appropriate health screening reminders and health education materials
 - Determine member threshold language needs to meet regulatory requirements

Using the Analysis Outside Wellpoint

- Reports and maps generated using the indirect race/ethnicity data process
 - Promote collaboration with its network medical groups
 - Promote partnering with external health advocacy organization like the American Cancer Society
 - Encourage open dialogues with elective government officials on the issue of health disparities and jointly work towards collaborative quality initiatives to reduce the gap in care

Looking toward the future

- Advancements in predictive abilities
 - Improved individual identification
 - Further granularity beyond major races (African-American, Hispanic, Asian, and White / Other) to major ethnicities (i.e. Chinese, Korean, etc.)
 - Language spoken predictions
 - Cultural assimilation
- Methodology Advancements
 - Explore use of updated name lists
 - Further explore the use of data mining tools such as tree models, neural networks, and other machine learning
- What are other industries doing?
