

# Getting Started with Map Algebra Using the Raster Calculator and Python

Nawajish Noman

# Poll the Audience

- How many of you use Spatial Analyst?
- How many of you are using Map Algebra prior to 10.x?
- How many of you know any Python?
- How many of you are writing stand alone Python scripts and/or script tools?

# Overview

- What is Map Algebra?
- Raster Calculator tool - Benefits of Map Algebra
- Python Window - Raster Object, properties and save
- Operators - What can '+' do?
- Complex equations - non SA, Boolean operators

# What is Map Algebra?

- Map Algebra is a language of arithmetic expressions using relations (operators and functions) and variables that represent spatial data and values.

- Is this a Map Algebra expression?

$$\text{Out} = A^{**} 2 / A\_max^{**} 2$$

A: Yes if A or A\_max is a spatial dataset then result, Out, will be a spatial result.

- What might B and C represent?

$$A = \text{Slope}(B * C)$$

$$B = \text{Raster}(\text{"elevation"})$$

$$C = 0.3048$$

# Demo: Raster Calculator

# Raster Calculator Recap

- Performance benefits!
- No intermediate results!
- Like any other GP tool - used in model builder and follows the same environment settings
- Basically Python inside the Raster Calculator
- Single line expressions – Keep it simple
- Python is case sensitive

# Demo: Python Window

# Python Window Recap

```
myElev = Slope("elevation", "DEGREE", 0.3048)
```

- Auto completion
- The input data type is a raster. (Layer or drag and drop from TOC or catalog)
- Drop down lists ("DEGREE", "PERCENT RISE")
- Strings are quoted in Python
- Numbers are not quoted
- Help – make sure you position it so you can see it
- Left hand result is a Raster Object

# Python Window Recap (continued)

- Raster Object

- Result is temporary

- Properties

- Save method

```
>>> mySlope.save("slopeout")  
>>> mySlope2.save("C:/data/slopeout2")
```

# Demo: Operators

The background features a vertical gradient from dark red at the top to bright orange at the bottom. In the lower half, there are layered, wavy shapes in shades of blue and purple. The bottom-most layer contains a faint, light blue grid pattern.

# Operators Test

Q1. Why are layers not cast as Raster objects in the Raster Calculator tool?

*A: They are cast as object but not by you*

Q2. Why doesn't the input to Slope have to be cast?

*A: It is a geoprocessing tool. The data type for the input parameter is a raster dataset*

Q3. What is the import statement needed to access Spatial Analyst operators?

*A: `from arcpy.sa import *`*

Q4. Bonus: Does it make sense to use the Raster Calculator in scripting? And why or why not?

*A: No, it is unnecessary because Map Algebra is now native to Python*

# Operator help documentation

- Use the web help, it is more up to date
- Make sure you know what the operator is doing
  - Boolean And is & (not AND) when working with raster, but is a 'bitwise and' when working with numbers
- Make sure you know the order of execution (precedence level)
- If your equation fails, add more parenthesis!

# Demo: (Complex) Expressions

The background features a warm orange-to-red gradient with a subtle, textured paper-like appearance. In the lower portion, there are layered, wavy shapes in shades of blue and purple. The bottom-most layer contains a faint, intricate geometric pattern of overlapping squares and lines, resembling a complex mathematical or architectural design.

# (Complex) Equation Recap

## 1) Using non spatial Analyst tools in Map Algebra

```
forest_ac =  
(ZonalStatistics(arcpy.Buffer_analysis("mills","#",1000),  
"OBJECTID","Forest","SUM"))* 0.000247
```

## 2) Using multiple relation and/or boolean operators

```
camps = ("dist_lake" < 2000) & ("dist_urban" > 5000)
```

## (Complex) Equations Recap (continued)

- Non Spatial Analyst
  - Result Object output
  - Managed output “#”
  - Not all tools that output a raster, output a raster object
- Multiple Relational and Boolean operators
  - Use brackets
  - Make sure you know the precedence level!

# Raster Calculator equations

What might these be used for?

1) `("pop" > 150) & ("dist" > 10)`

2) `(("reclass_rd_dist" * 3) + ("reclass_landuse" * 2) + "reclass_elev") / 6.0`

3) `("Band4" - "Band3") / Float("Band4" + "Band3")`

4) `Con(("elev" <= 3000), 1, 0)`

5) `Con(IsNull("elev"), 0, "elev")`

# Complex RC Equation Test

1) Where do the brackets go?

```
Con "landuse1" == 1 & "landuse2" == 5, 0, 1
```

```
A: Con(("landuse1" == 1) & ("landuse2" == 5), 0, 1)
```

2) What is another way to do this analysis?

```
Con("elev", 1, 0, "VALUE <= 3000")
```

```
A: Con(Raster("elev") <= 3000, 1, 0)
```

# What is wrong with these expressions

(Or how can you improve them?)

- `Con("elev" > 1500, 1, 0)`
- `(Raster("dist_wat") < 1000) AND (Raster("dist_forest") < 500)`
- `Raster("dist_wat") < 1000 & Raster("dist_forest") < 500`
- `>>> a = "layer" + 3`
- `mySlope = Slope("input", "output", "DEGREES", 0.348)`
- `mSlope2 = Slope("input", "DEGREES", "0.348")`
- `import arcpy.sa`
